1. I chose to look at the average Influenza deaths for all years. I did this because there is no significant relative change to the choropleth map when looking at specific months or years.
4.
  - a) Over the period of the data set there is no real change between the states, when it comes to influenza deaths: The same states always have the highest number of deaths. New York and California have the **highest influenza deaths**, the **highest number of deaths for those aged 65+** and the **largest populations for the 65+ age group**. Texas has about the same number of Influenza deaths as Maine, but around 20% larger population in the 65+ age group. Alaska has the lowest number of influenza deaths, but not the lowest of the low population states, like Vermont or North/South Dakota.
  - b) As I could tell there are no significant differences, when comparing influenza deaths between the five categories, through the different years.
